

Bang & Olufsen

BEOMASTER 1900
TYPE 2903/4

SERVICE MANUAL

INTRODUCTION

In the diagrams each component is provided with an individual position number and a co-ordinate designation, e.g. B3. This designation refers to the position on the PC board which is provided with a printed division into spaces and with letters and figures along the edge of the PC board. For the two amplifier channels the two last digits of the position numbers are identical. Left channel begins with 200, right channel with 300.

TECHNICAL DATA
AMPLIFIER

Power output 1000 Hz RMS	2 x 30 W/4 Ohms
	2 x 20 W/8 Ohms
Music power	2 x 50 W/4 Ohms
	2 x 30 W/8 Ohms
Speaker impedance	4 Ohms
Harmonic distortion	
1000 Hz, 50 mW	< 0,07%
DIN 45 500, 40 - 12.500 Hz	< 0,13%
Intermodulation DIN 45 500	< 0,15%
Frequency range \pm 1,5 dB DIN 45 500	20 - 40.000 Hz
Power bandwidth, 1% distortion	10 - 40.000 Hz
Damping factor 1000 Hz	> 70
Input pick-up	3 mV/47 KOhms
Input tape	220 mV/470 KOhms
Signal-to-noise ratio DIN 45 500	
50 mW, pick-up	> 60 dB
50 mW, tape recorder	> 65 dB
Channel separation 1000 Hz, DIN 45 500	> 56 dB
250 - 10.000 Hz	> 38 dB
Output, tape recorder 1000 Hz, DIN 45 500	100 mV/100 KOhms
Headphones	Max. 6 V/200 Ohms
Bass control at 40 Hz	\pm 18 dB
Treble control at 12.500 Hz	\pm 15 dB

FM

FM range	87,5 - 108 MHz
Sensitivity, stereo 46 dB	< 30 μ V/75 Ohms
Signal-to-noise ratio, stereo, weighted	> 60 dB
Frequency range DIN 45 500, \pm 1,5 dB	20 - 15.000 Hz
Harmonic distortion DIN 45 500	< 0,4%
Stereo channel separation 1000 Hz	> 35 dB
Pilot suppression 19 KHz	> 45 dB
38 KHz	> 50 dB

OTHER DATA

Power supply	110 - 130 - 220 - 240 V
Power consumption	25 - 185 W
Dimensions W x H x D	62 x 6 x 25 cm
Weight	7,6 kg

Subject to change without notice

MÅLEBETINGELSER FOR DIAGRAM:

Alle DC spændinger er målt i forhold til stel med voltmeter (indre modstand 11 MΩ).

DC spændinger *uden* parentes er målt med modtageren i stilling FM 5 og antennesignal på 500 µV (1 mV EMK) med pilottone.

VOLUME i stilling MEDIUM og højttalere *ikke* tilsluttet.

DC spændinger *i* parentes på 2IC9 er målt, når et af betjeningsfelterne aktiveres.

DC spændinger *i* parentes på 2TR30, 2TR31 og 2TR32 er målt i stilling STAND BY.

FM signalniveauer er målt ved Δf 40 kHz, f mod. 1 kHz og antennesignal på 500 µV (1 mV EMK).

LF følsomheder er målt ved 30 W output. Balance, bas, diskant på 0, volume på max. Udgang belastet med 4 Ohm, input 1 kHz.

CONDITIONS OF MEASUREMENT FOR DIAGRAM:

All DC voltages are measured in proportion to chassis with voltmeter (inner resistance 11 MΩ).

DC voltages *without* bracket are measured with the receiver in position FM 5 and aerial signal 500 µV (1 mV EMK) with pilot signal.

Volume in position MEDIUM and speakers *not* connected.

DC voltages *with* brackets on 2IC9 are measured when one of the operating fields is activated.

DC voltages *with* brackets on 2TR30, 2TR31 and 2TR32 are measured in position STAND BY.

FM signal levels are measured at Δf 40 kHz, f mod. 1 kHz and aerial signal 500 µV, (1 mV EMK).

LF sensitivities are measured at 30 W ouput. Balance, bass treble on 0, volume on max.

Output loaded with 4 Ohm, input 1 kHz.

MESSBEDINGUNGEN FÜR SCHALTBILD:

Alle DC Spannungen sind im Verhältnis zu Chassis mit Voltmeter (innerer Widerstand 11 MΩ) gemessen.

DC Spannungen *ohne* Klammern sind mit dem Empfänger in Stellung FM 5 und Antennensignal von 500 µV (1 mV EMK) mit Pilotten gemessen.

Volume in Position MEDIUM und Lautsprecher *nicht* angeschlossen.

DC Spannungen *in* Klammern auf 2IC9 sind gemessen, wenn eines der Bedienungsfelder aktiviert wird.

DC Spannungen *in* Klammern auf 2TR30, 2TR31 und 2TR32 sind in Position STAND BY gemessen.

FM Signalniveaus sind bei Δf 40 kHz, f mod. 1 kHz und Antennensignal von 500 µV (1 mV EMK) gemessen.

LF Empfindlichkeiten sind bei 30 W Output gemessen. Balance, Tiefton, Diskant auf 0, Volume auf max. Ausgang mit 4 Ohm belastet, Eingang 1 kHz.

TESTPUNKTER/TESTPOINTS/ TESTPUNKTE

2TP2	IF signal	2TP202	12 mV

ADJUSTMENTS
15-VOLT SUPPLY

With the receiver switched to FM, adjust 2R151 so that 15 volts is present at 2TP15.

NO-SIGNAL CURRENT

No-signal current is adjusted while the receiver is cold and with the volume control turned down.

Speakers must not be connected.

With 2R249 (2R349) adjust for 25 mA collector current in 2IC200 (2IC300) or - 12 mV across 2R256 (2R356).

When the receiver has been on for ten minutes, with the volume control turned down, check the no-signal current and again adjust for 25 mA or 12 mV across the emitter resistor.

TUNING VOLTAGE

With receiver switched to FM 1 and potentiometer 4R3 turned against the stop at 88 MHz, adjust 4R2 so that 4.5 volts is present at 4TP1.

With receiver switched to FM 5 and potentiometer 4R7 turned against stop at 88 MHz, adjust 4R8 so that 4.6 volts is present at 4TP1.

VHF TUNER

Set tuning control to 89 MHz and sweep generator to 89 MHz.

With 1L1, 1L2, 1L3 and 1L9 adjust for max. IF curve at 2TP2.

Set tuning control to 106 MHz and sweep generator to 106 MHz.

With 1C1, 1C6, 1C9 and 1C20 adjust for max. IF curve at 2TP2.

Check dial accuracy and repeat adjustment if necessary.

Set tuning control to 97 MHz and sweep generator to 97 MHz. With 1L5 and 1L6 adjust for max. IF curve at 2TP2.

Adjust 2L2 for max. S-curve, measured at 2TP3.

Set tuning control so that no signal is being received and adjust 2L3 so that 0 volts is present at 2TP3.

DETECTOR

BALANCE LIGHT

Short 2TP3 to chassis and adjust 2R31 for equal brightness of the two lamps.

DECODER

Short 2TP3 to chassis.

With 2C24 adjust the internal oscillator to exactly 19 kHz as measured at 2TP4.

The accuracy can be checked in two ways:

1 Connect frequency counter to 2TP4.

2 Apply 19 kHz from 2TP4 to y-input of oscilloscope and 19 kHz from a stereo decoder to x-input of the oscilloscope.

When the Lissajous figure is stationary, adjustment is correct.

A third possible way to adjust the internal oscillator is as follows:

3 Remove short-circuit and tune receiver to a stereo program.

Turn 2C24 to one side until the stereo lamp turns off. Thereafter turn 2C24 to the other side until the stereo lamp turns off.

The setting midway between these two settings represents correct adjustment.

Coil 2L4 is factory pre-adjusted to 114 kHz and should not be touched.

CHANNEL SEPARATION

Connect stereo decoder to aerial input, $f \text{ mod } 1 \text{ kHz}$, $\Delta f 40 \text{ kHz}$, pilot 8-10%, AFC on.

Connect wattmeter to amplifier output. Treble control at min.

With 2R29 adjust for min. output in the unmodulated channel. Make this adjustment both with unmodulated left channel and unmodulated right channel.

ADJUSTMENT OF LEVEL

Volume set at MEDIUM and receiver switched to TAPE.

Connect tone generator to TAPE input, 200 mV, 1 kHz. Connect millivoltmeter to speaker output. With 2R136 adjust for 1.00 mV at output.

DESCRIPTION
BEOMASTER 1900

This description covers the switch functions, muting circuits and counter circuits for volume regulation. The other circuits are considered known and therefore will not be described.

STAND BY

When the on/off switch is operated, 15V stabilised appears at the collector of 2TR27. 15V stand by is brought out to the PROGRAM SELECTION circuit and the anode of 5D1 (stand by indicator), which lights. Return current is fed through 5R1 and dial lights 7IL1-2-3. The set is now ready to receive orders. Orders can be given by touching the control fields.

ON

When one of the control fields is touched, the EL. SWITCH, 2TR31 and 2TR32, is activated via 2IC9; also, the relay is energised, applying supply voltage to the rest of the receiver; $\pm 31V$ unstabilised is applied to the output amplifier, $-12V$ to EL. VOLUME CONTROL, 27V to FM tuning, and 15V to tuner, IF, decoder, pre-amplifier, tone amplifier, and PROGRAM INDICATION. The stand by indicator turns off when 15V appears at the cathode.

In addition to the application of supply voltage, a pair of switch diodes, 2D200, 2D300, are activated, enabling the signal to pass on to the amplifier. Furthermore the 15V are applied as supply voltage to 2IC5 and 2IC6 through 2D20. Apart from reducing the voltage, 2D20 prevents noise impulses on the supply rail from causing the IC to change program. This will happen if the supply voltage briefly becomes higher than the voltage on the input.

PROGRAM SELECTION

The heart of the circuit is a 100 kHz oscillator, 3TR7, 3L1 and 3C7. The oscillator coil supplies 100 kHz power to the transistors of the PROGRAM SELECTION circuit, 2TR15 - 2TR22.

The amplitude of the 100 kHz voltage at the emitter of 2TR21 is approx. 3V rms whilst approx. 6V rms is present at the top of 3L1.

This voltage is fed to the base of 2TR21 through 2C85. The base is connected to the FM 5 control field through a solder terminal and a bronze spring.

The capacitance of 2C85 is 3.3 pF because C spread is 3.3 pF. This provides a division of the 6V voltage so that 3 V will be present at the base just like at the emitter. Hence balance exists between the emitter and base, and the transistor is OFF.

When the control field is touched, a different capacitance to chassis potential will exist (approx. 7 pF). This affects the voltage division ratio so that a lower amplitude is now present at the base than at the emitter, causing the transistor to go ON during the half-cycles in which the base is positive relative to the emitter.

This will result in a flow of pulsating current in the direction of the arrows, and the same amount of collector current will flow in the transistor. This pulsating current is integrated across 2C84, and a voltage drop occurs at the collector of 2TR21.

Supply voltage for 2TR21 is obtained through 2R100 and 2R124. When the collector of 2TR21 goes towards chassis potential, the base of 2IC9 will likewise go towards chassis. This will cause the base/emitter voltage to increase, and 2IC9 goes ON.

As long as the control field is touched, a current flows from the collector of 2IC9 to the base of 2TR32. 2TR32 will go ON, drawing its current from the base of 2TR31 through relay coil 8RL1. The relay operates, applying supply voltage, + and -31 V, to the output and -12 V to the volume-control counter circuit. Simultaneously, 2TR31 goes ON and receives 15 V at its collector. This causes 2TR32 to receive constant base bias through voltage divider 2R155 - 2R156; the transistor is ON; and the FM 5 setting is locked. Supply voltage is now applied to the entire receiver. The stand by indicator, SD1, turns off, 15 V now being present on both sides.

In addition to activating the power supply to the rest of the receiver, the negative voltage jump at 2TR21 is also applied to pin 14 of 2IC6 through 2R126.

When pin 14 of 2IC6 goes towards chassis potential, a positive-going pulse appears at pin 2 across 2R47. This causes the preceding program to be turned off. Simultaneously therewith, a positive voltage appears at pins 13 and 4.

From pin 13, the voltage is fed to 5TR7, which goes ON, and lamp 5IL10 (FM 5) lights.

From pin 4, tuning voltage is fed up to the tuning potentiometer, 4R7. In addition, the voltage at pin 4 is fed through 2D9 and 2R42 to 2D202. The diodes receive forward bias, allowing the FM signal to pass. Simultaneously with this, 2D200 (phono) and 2D201 (tape receive reverse voltage, thereby preventing the passage of any signal on these programs. The same voltage is employed as base bias for 2TR1 and 2IC3.

OFF

The receiver is turned off by touching the stand by field. The resulting voltage drop at the collector of 2TR22 passed via 2D37 and 2R130 to pin 16 of 2IC6.

At pin 15 there now appears a positive voltage, which is fed to muting transistor 2TR207 through 2D53. The muting transistor goes ON, and the signal is shorted to chassis potential.

2D37 insures during "Switch OFF" that the 2IC6 input pin 16 is held below the supply voltage, as otherwise the positive voltage on output pin 15 would disappear and thus preventing the apparatus from going in "Stand by".

Furthermore, the voltage is fed to the output stage FAULT SWITCH 2TR25 and 2TR26. 2TR25 goes ON, the collector is placed at chassis potential, which potential is transmitted to 2TR32 in EL SWITCH.

2TR32 goes OFF, relay 8RL1 releases, and the supply voltage for the output stages disappears. 2TR31 also goes OFF, and the 15 V supply voltage at the collector disappears. From now on, supply voltage is present only at the PROGRAM SELECTION circuit.

MUTING WHILE SWITCHING ON

When the set is in stand by, 15 V is present at the collector of 2TR30 and 2C98 carries a charge. The 15 V at the collector keeps the muting transistors, 2TR207 and 2TR307, ON so that any signal is shorted to chassis potential as long as the set is in stand by.

When a program is selected, 2TR30 goes OFF and the 15 V potential disappears from the muting transistors. However, the muting transistors are kept ON until 2C98 is discharged. Discharge occurs through 2D54 and resistors 2R238 and 2R338; the discharge time is determined by these components and is approx. 200 msec.

When stand by is activated, 2TR30 goes ON and 2C98 charges again through 2R154.

MUTING WHILE SWITCHING PROGRAMS

When switching programs there appears across 5R3 a positive voltage jump which is applied to the base of 3TR6. 3TR6 goes OFF, causing -12 V to be present at its collector. The -12 V potential is applied via 2R141 and 2R157 to the muting transistors, 2TR206 and 2TR306, which go OFF, thus blocking the signal path.

This remains blocked until 3C6 is discharged, which lasts approx. 500 msec. 3D11 secures that 3C6 will not discharge through 5R3 but only through 3R26.

MUTING WHILE SWITCHING OFF

When the set is switched off, the positive pulse appearing at pin 15 of 2IC6 is fed to muting transistors 2TR207 and 2TR307, causing them to go ON. Simultaneously therewith the 15 V supply voltage disappears, and 2TR30 goes ON. The 15 V potential at the collector of 2TR30 thereafter provides base bias for 2TR207 and 2TR307 and keeps them ON as long as the set is in stand by.

FAULT SWITCH

In the event of faults in the output, the circuit, 2TR25 and 2TR26, will cut off the supply voltage, and the set will go into stand by. If a positive DC voltage appears at the output, in either the left or right channel, 2TR25 will go ON, and the collector will be at chassis potential. This will cause 2TR32 to go OFF; the relay releases and the supply voltages disappear.

If the DC voltage appearing at the output is a negative one, 2TR26 will go ON. The emitter receives a negative voltage as a result of which 2TR32 goes OFF, the relay releases and the supply voltages disappear. 2D49 ensures that 2 TR26 will not go ON without reason.

VOLUME CONTROL WITH PHOTORESISTORS

Volume control by means of sensitouch requires either a motor-driven potentiometer or some form of electronic control.

meter or some form of electronic control. The system selected for the Beomaster 1900 is electronic control by means of photoresistors, so-called LDR's (light-dependent resistors). The photoresistors, four in all, are physically grouped around the same lamp, which thus controls in both left and right channels.

When under strong light the resistors have a value of a few hundred ohms. Decreasing light intensity causes an increase in resistance, reaching several megohms in darkness.

Circuitwise, the resistors are connected as shown:

The mode of operation is as follows:

Looking at the left channel:

If the photoresistors receive no light, their resistance is very high, and the signal passing through 2R226 continues unobstructed to the tone amplifier and from there through 2R233 to the output amplifier.

This situation corresponds to full-on volume.

If the photoresistors are thereafter illuminated their resistance will be lower, and only part of the signal from 2R226 will go into the tone amplifier because of the voltage division taking place between the photoresistor 2R200 and 2R226. The same condition exists in the output amplifier.

The lamp is powered from an adjustable lamp driver circuit.

At max. volume, approx. 1 V is present across the lamp; at min. volume, approx. 5 V.

The resulting control range is 70-75 dB.

A defective lamp will correspond to max. volume. To prevent this, the collector of 2TR24 is connected to 3TR6 via 2D47.

If the lamp filament breaks, the collector voltage of 2TR24 will disappear. The emitter of 3TR6 goes towards zero via 2D47, causing 3TR6 to go OFF. At the collector there now appears -12 V, which is fed to the muting transistors, 2TR206 and 2TR306, which go OFF, and the receiver is muted.

Volume regulation is carried out by altering the base bias of 2TR23. This means that we need a circuit that is capable of altering this voltage upwards or downwards as long as we touch the volume control and thereafter locking the voltage until we again want a volume change.

For this purpose we employ a binary counter circuit, MC 14516, which can count in both directions.

It is an integrated circuit. We are not going to discuss what it contains. We just want to study its properties.

The sketch shows the counter IC. It is connected between chassis potential and $-12V$. There are four outputs, $Q_A - Q_B - Q_C - Q_D$. These outputs can assume only two voltage values, either $-12V$ or $0V$. In digital parlance an output is said to be low when it has assumed its most negative value, and high when it has assumed its most positive value. Alternatively, these two states are called 0 and 1, respectively, which is what we will do below. Therefore: a zero represents $-12V$ and a figure one represents $0V$.

Since it is therefore possible for each for output to have two positions we shall have a total of $2 \times 2 \times 2 \times 2 = 16$ combinations.

In system form it looks like this:

Q _D	Q _C	Q _B	Q _A
0	0	0	0
1	0	0	1
2	0	0	0
3	0	0	1
4	0	1	0
5	0	1	0
6	0	1	0
7	0	1	1
8	1	0	0
9	1	0	1
10	1	0	0
11	1	0	1
12	1	1	0
13	1	1	0
14	1	1	1
15	1	1	1

This set-up is called the binary code. Q_A is called the least significant digit, and Q_D is called the most significant digit.

The counter is designed so that it will itself run through these combinations when ordered to do so. It does this by feeding a series of pulses from a clock generator to pin 15.

The clock generator is a multivibrator whose pulses have the appearance shown in the sketch below.

When +12 V is applied to 3R3 or 3R4, the multivibrator starts. If -12 V is fed to 3R3 or 3R4, the multivibrator blocks.

The counter switches from one combination to the next every time the clock voltage jumps from -12 V to 0 V.

If pin 10 of the IC is connected to chassis potential the IC will count in the direction from 0 to 15. If, on the other hand, pin 10 is connected to -12 V the counter will count in the direction 15, 14, 13, 0.

On reaching one of its extreme positions, the counter turns round; that is, it starts all over again. For example, 12 - 13 - 14 - 15 - 0 - 1 - 2 etc.

DIGITAL/ANALOG CONVERTER

By means of four resistors we alter the voltages at Q_A , Q_B , Q_C , and Q_D to a voltage analogous with the number at which the counter happens to be at the particular moment.

Each output connects through a resistor to a common junction. The resistance values have been chosen so that the most significant digit Q_D has the lowest resistance connected to it. the most important but one has a resistance that is twice as high, etc.

It is easily seen that the voltage at the junction will be 0V in one extreme position and $-12V$ in the other extreme position. For all other positions the voltage will assume some value between $-12V$ and 0V.

The change will take place in jumps so a graphical representation would have the appearance of a staircase.

However, we smooth down the staircase with 3C5 so that the volume variation will not take place in audible jumps.

VOLUME CONTROL PRESET

In addition to having four outputs, the IC also has four inputs, A, B, C, and D, which may be used for programming the IC. We are going to make use of this because we want the receiver to set itself to a preset volume when started up.

The A input we fixed at $-12V$. That is, 0 in digital parlance.

B, C, and D have also been fixed at $-12V$, but through a 100 kohm resistor each of them. Furthermore, B, C, and D are connected to a preset switch.

The switch allows us to set the input in the following combinations:

H 0110
M 1000
L 1010

The combination selected will automatically be transmitted to the outputs when we start the receiver. The fact is that the outputs will set themselves to be equal to the inputs if the voltage at pin 1 has the digital value of 1, which it has during start, as pin 1 is connected to chassis potential through a $1\mu\text{F}$ capacitor, 3C4.

A fraction of a second after start, pin 1 has dropped to 0 on account of 3R16, and the IC is ready to count.

UPWARD REGULATION OF VOLUME

END STOP:

The IC carries a marking as to whether it is in one of the extreme positions. This marking is the voltage at pin 7.

Normally, pin 7 is 1, but when we reach one extreme position (max. volume), where the outputs are 0000, pin 7 is also 0.

In the other extreme position (min. volume), where the outputs are 1111, pin 7 is also 0.

In all other positions, pin 7 is 1.

The pin 7 output may now be added to the combination table as shown:

Counter position	Pin 7	QD	QC	QB	QA
0	0	0	0	0	0
1	1	0	0	0	1
2	1	0	0	1	0
3	1	0	0	1	1
.
12	1	1	1	0	0
13	1	1	1	0	1
14	1	1	1	1	0
15	0	1	1	1	1

It will be seen that in the 0 position, pin 7 and QD have the combination 00. In the 15 position, the combination is 01.

In other words: the combination of pin 7 and QD tells us whether we are in an extreme position, and also which one.

We make use of this fact for stopping the multivibrator when we reach one of the extreme positions.

Which way will the current flow now? Well, that depends on whether the voltage on the other side of 3D5 is high or low.

If the voltage is low, the current will flow through 3D5 and 3R14 to $-12V$, and the multivibrator will not start up.

If, on the other hand, the voltage is high, 3D5 is cut off, and the current will flow into the multivibrator and start it up.

In order for the multivibrator to run, therefore, the voltage at the junction of 3D5, 3D8 and 3D10 must be high. When is it high? It is high if: Q_D is 1, pin 7 is 1 or both Q_D and pin 7 are 1. The voltage is low if both Q_D and pin 7 are 0, and it is low only in the 0 position. Accordingly, the multivibrator can run until the 0 position is reached; then it stops.

DOWNTWARD REGULATION OF VOLUME

END STOP

This function is somewhat similar to the one just described.

Pin 10 of the IC is connected to chassis potential through 3R15; that is, pin 10 is 1: this means that the counter is now ready to count upwards, giving lower volume.

If we touch the "Down" field, 3TR10 and 3TR8 will draw current, which will start the multivibrator if the voltage at the junction of 3D6, 3D9 and the collector of 3TR3 is high, and it will be high if: the collector of 3TR3 is 1, or pin 7 is 1, or both are 1.

TIMING DIAGRAM

For 3TR3 it applies that the collector is 1 when QD is 0 and vice versa. To stop the multivibrator, pin 7 must be 0 and QD 1; that is, the combination 01. This is obtained in the 15 position, so the multivibrator stops here.

MUTING

In the 15 position, or min. volume, the voltage at the junction of 3D6, 3D7 and 3D7 is low, which fact is utilised for muting the receiver. The -12V potential is fed via 3D7 to the muting transistors, 2TR206 and 2TR306, which go OFF and in so doing block the signal.

VOLUME INDICATION

When volume is regulated upwards the voltage at the base of 3TR5 goes towards -12V. The collector voltage goes in the positive direction. This voltage change is transmitted to the base of 3TR13 and via 3D13 to the lamp driver circuit, which makes the voltage across 2IL1 drop and in so doing makes the volume increase.

The voltage change at the base of 3TR13 is also employed for lamps 6IL1 and 6IL2.

The voltages are measured in the MEDIUM position, and volume is regulated from the MEDIUM position upwards.

When the voltage at the base of 3TR13 becomes more positive, the base/emitter voltage drops, and 3TR13 is OFF.

The voltage at the base of 3TR12 becomes more positive too as a result of which 3TR12 will draw more current and 6IL2 become brighter.

If volume is regulated from the MEDIUM position downwards, the voltage at the base of 3TR13 will move in the negative direction. This will make 3TR13 go ON and 6IL1 become brighter.

MODIFICATIONS

FASTENING OF HEAT SINKS

The heat sinks are fastened to the chassis by means of screws and washers.

Screw No. 2013024

Washer No. 2622261

The change has been introduced from No. 189001.

CHANGE OF TUNING VOLTAGE

From apparatus No. 248001 2D19 has been changed to No. 8340105 which is the same type of diode, but with a larger voltage, 27.5V - 29.5V. This means that the tuning voltage must be adjusted to a larger voltage:

FM1, 4R2 to be adjusted to 4.7V

FMS, 4R8 to be adjusted to 4.8V.

SERVICE TIPS

SENSITIVITY ON THE OPERATING FIELDS

The oscillator coil, 3L1, has in production been adjusted to 3.2 Volts measured in 3TP2 with voltmeter ($R_i \geq 1$ Mohm).

If the sensitivity on the operating fields is too low, the voltage in 3TP2 may be increased to max. 3.5 Volts.
